

# INDUCTION ON TREES AND GRAPHS

W. PATRICK HOOPER

The goal of these notes are to give some more examples of rigorous inductive arguments involving trees and graphs, following [Lev21]. The following result is crucial for arguments involving induction on trees:

**Proposition 1** ([Lev21, Prop. 4.2.3]). *If a tree has at least two vertices, then it has at least two vertices of degree one.*

A vertex of a trees with degree one is also called a *leaf*. Removing a leaf and the incident edge leads to a tree with one fewer vertex (because the resulting subgraph is clearly still connected and doesn't have cycles).

The book gives a good careful inductive proof of the statement that all trees satisfy  $v = e + 1$ , where  $v$  is the number of vertices and  $e$  is the number of edges [Lev21, Prop. 4.2.4]. Levin uses rooted trees to prove the following result, but we will use induction.

**Proposition 2.** *Every tree is bipartite.*

Recall that a graph is bipartite if its vertex set can be split into two disjoint sets  $A$  and  $B$  and every edge has the form  $\{a, b\}$  where  $a \in A$  and  $b \in B$ . (That is, there are no edges joining vertices in the same set.)

*Inductive Proof.* For each integer  $n \geq 1$ , let  $P(n)$  be the statement that every tree with  $n$  vertices is bipartite. To prove this statement by induction we need to prove both:

- $P(1)$ . That is, we need to prove every tree with one vertex is bipartite.
- For every  $k \geq 1$ ,  $P(k) \implies P(k + 1)$ . That is, we can assume that if every tree with  $k$  vertices is bipartite, and we need to prove that every tree with  $k + 1$  vertices is bipartite.

**Base case:** We will show that every tree with one vertex is bipartite. Let  $T$  be a tree with 1 vertex. Then we can place that vertex in set  $A$  and define  $B$  to be the empty set. Since there are no edges, this tree is bipartite.

**Inductive step:** Assume every tree with  $k$  vertices is bipartite. We will show that every tree with  $k + 1$  vertices is bipartite. Let  $T$  be a tree with  $k + 1$  vertices. Since  $k + 1 \geq 2$ , we know that  $T$  has at least two leaves. Choose one leaf and call it  $v$ . Let  $w$  be the other endpoint of the single edge of the leaf  $v$ . Let  $T'$  be the subgraph obtained by removing  $v$  and the edge  $\{v, w\}$ . Then  $T'$  is a tree with one fewer vertex, so by our inductive assumption  $T'$  is bipartite. This means we can split the vertices of  $T'$  into two subsets,  $A' \cup B'$ , and all edges have the form  $\{a', b'\}$  with  $a' \in A'$  and  $b' \in B'$ .

We need to write the vertices of  $T$  as a union of two sets with all edges going between vertices from different sets. Note that  $w$  is a vertex of  $T'$ . To show  $T$  is bipartite, we break into two cases. First suppose  $w \in A'$ . Then we define

$$A = A' \quad \text{and} \quad B = B' \cup \{v\}.$$

FIGURE 1. A graph with four components.

Then all the vertices are in  $A \cup B$ . To see this makes  $T$  bipartite, consider any edge  $e$  of  $T$ . If  $e$  is an edge of  $T'$  then  $e$  has one vertex in  $A'$  and one in  $B'$ , so it also has one in  $A$  and one in  $B$ . If  $e$  is not an edge of  $T'$ , then  $e$  must be the edge  $\{v, w\}$  and  $v \in B$  and  $w \in A$ . This shows  $T$  is bipartite. The second case is when  $w \in B'$ . In this case we define

$$A = A' \cup \{v\} \quad \text{and} \quad B = B'.$$

Then again any edge of  $T$  is either an edge of  $T'$ , which has one vertex in  $A$  and one in  $B$  like before, or is the edge  $\{v, w\}$  and here we have  $v \in A$  and  $w \in B$ . So again  $T$  is bipartite.  $\square$

**Remark 3.** *Instead of breaking into two different cases in the last paragraph above, we could have said “To show  $T$  is bipartite, assume without loss of generality that  $w \in A'$ ” and worked through only the first case. This expression is just to indicate that there are multiple cases, but there is a symmetry (or the objects can be relabeled) to see that the multiple cases work in exactly the same way. Here, the names we are using for the two sets  $A'$  and  $B'$  are arbitrary, so if  $w \in B'$ , then we could swap the names of the sets  $A'$  and  $B'$  to get that  $w \in A'$ . You can see that the second case is really the same as the first case but with the roles of  $A'$  and  $B'$  swapped.*

Now recall that if  $G$  is a graph a *spanning tree* is a subgraph that is a tree and includes all vertices of  $G$ . We’ll give a formal proof of:

**Theorem 4.** *Every connected graph has a spanning tree.*

We’ll give an inductive proof of this. The main idea is given a graph  $G$  we can pick any edge  $e$  of  $G$  and remove just that edge (leaving the endpoints). This results in a subgraph  $G'$  with one fewer edge. But the graph  $G'$  may not be connected. So, this is a problem for us running a simple inductive argument like the inductive argument like the one above.

We need some new terminology. If  $v_1$  is a vertex of the graph  $G'$ , then the *component* of  $G'$  containing  $v_1$  is the subgraph consisting of all vertices and edges that can be reached by paths passing through  $v_1$ . Each component is connected (because each vertex of the component has a path to  $v_1$ ). See Figure 1 for an example. A graph is connected if and only if it has only one component.

Removing an edge from a connected graph can result in either a connected graph or a graph with two components (the components of the two endpoints). See Figure 2.

We will apply our inductive hypothesis to the components a graph  $G$  with an edge removed. This subgraph  $G'$  is either connected, in which case  $G'$  has one fewer edge than  $G$ , or  $G'$  consists of two components and the sum of the edges of the two components is one fewer than the number of edges of  $G$ .

FIGURE 2. The graph here is connected, but removing the red edge results in a subgraph with two components.

*Inductive Proof of Theorem 4.* Let  $P(n)$  be the statement “every connected graph with  $n$  edges has a spanning tree.” We’ll prove that  $P(n)$  is true for all  $n \geq 0$  using strong induction. To do this we will show:

- $P(0)$  is true.
- For every  $k \geq 0$ , if  $P(i)$  is true for all  $i$  with  $0 \leq i \leq k$ , then then  $P(k + 1)$  is true.

**Base case:** Suppose our connected graph  $G$  has zero edges. Then it must consist of a single vertex. A graph with a single vertex and no edges is a tree, so  $G$  is its own spanning tree.

**Inductive step:** Let  $k \geq 0$ . Assume that every connected graph with  $k$  or fewer edges has a spanning tree. We’ll show every connected graph with  $k + 1$  edges has a spanning tree. Let  $G$  be a graph with  $k + 1$  edges. We’ll prove  $G$  has a spanning tree.

Pick any edge  $e$  of  $G$ . Let  $G'$  be the subgraph formed by removing  $e$  from  $G$  and keeping all vertices and all other edges. Then  $G'$  has  $k$  edges. As noted above,  $G'$  either is connected or consists of two components. We break into these cases below.

First suppose  $G'$  is connected. Then from our inductive hypothesis,  $G'$  has a spanning tree  $T'$ . This means that  $T'$  is a subgraph which is a tree that includes all the vertices of  $G'$ . Then  $T'$  is also a subgraph of  $G$  and has all the vertices of  $G$ , so  $T'$  is also a spanning tree for  $G$ .

Now suppose that  $G'$  consists of two components. Call these components  $G'_1$  and  $G'_2$ . Let  $E'_1$  and  $E'_2$  denote the edge sets of these two components, respectively. Then  $|E'_1| + |E'_2| = k$ , so both graphs have  $k$  or fewer edges. Therefore by inductive hypothesis we can find a spanning tree  $T'_1$  for  $G'_1$  and a spanning tree  $T'_2$  for  $G'_2$ . Now define  $T$  to be the subgraph of  $G$  consisting of  $T'_1$ ,  $T'_2$  and the edge  $e$  we removed. This subgraph  $T$  has all the vertices of  $G$  because every vertex of  $G$  is either a vertex of  $G'_1$  or of  $G'_2$  and  $T'_1$  and  $T'_2$  contain all the vertices of the components containing them. We also claim that  $T$  is a tree. The subgraph  $T$  is connected, because both  $T'_1$  and  $T'_2$  are connected and the edge  $e$  we added allows us to move from  $T'_1$  back and forth to  $T'_2$ . Any cycle in  $T$  would have to be contained in  $T'_1$  (which is impossible because  $T'_1$  is a tree), be contained in  $T'_2$  (which is likewise impossible), or as we travel around the cycle we travel from  $T'_1$  to  $T'_2$  and then back again to  $T'_1$ . But the only way to travel from  $T'_1$  to  $T'_2$  or back is through the edge  $e$  and cycles can’t repeat edges, so this third possibility is also impossible. This proves that  $T$  is a tree and a spanning tree for  $G$ .  $\square$
